

OSIS: Open System Integration Server – the Product range –

OSIS, the Open System Integration Server, is associated with a modern and, as proved by many customer orientated projects, reliable technology for the IT system integration. As a result of the modular OSIS product range, the OSIS server can be assembled to meet the individual requirements for an optimal business integration server. OSIS enables a “small start” with successive upgrading until eventually a professional business interface management system is achieved.

With OSIS the individual interface programming required for the process chain is replaced with the configuration of an intelligent technology. This and other performance characteristics such as the central control, administration, monitoring of the completely automated data flow in the productive environment, lead to a high quality, transparent and reliable information flow at the process chain interfaces with greatly reduced project costs and operative expenses.

Examples for the IT solutions with the use of OSIS are:

- The cross-linking of company internal processes via the integration of several IT applications (EAI), for example with standard software (i.e. SAP Systems), with individual software or legacy systems or direct with SQL databases. At the same time the data exchange between unlimited company internal IT systems and external systems enables the integration of external partners.
- The integration of unlimited company internal IT systems for the carrying out of business processes via the internet and the World Wide Web.
